(Received 22 August 1995; accepted in final form 1 September 1995)

**Abstract**—This paper deals with the solution of the title problem in the case where the outer boundary is subjected to uniform, hydrostatic pressure while the inner edge of the plate is free. It is assumed that the plate thickness varies (a) in a discontinuous fashion and (b) linearly.

An approximate approach is proposed using polynomial coordinate functions which identically satisfy the boundary conditions at the outer edge, only. The eigenvalues are determined using the optimized Rayleigh–Ritz method and good engineering agreement is shown to exist with buckling parameters obtained by means of a finite element code.

### 1. INTRODUCTION

The technical literature contains very limited information on critical, buckling loads of the structural systems shown in Fig. 1 (Timoshenko and Gere, 1961). Even in the case of the annular plate of uniform thickness the buckling parameter available in the open literature, has been determined for Poisson's ratio ( $\nu$ ) equal to 1/3.

The problem is of great practical significance in civil, mechanical, naval and ocean engineering applications.

This paper presents a very simple methodology to tackle this rather complex elastic stability problem. Numerical data is obtained for plates of uniform thickness,  $h_0$ , and plates of non-uniform thickness, Fig. 1a and Fig. 1b, for several values of Poisson's ratio.

### 2. APPROXIMATE SOLUTION BY MEANS OF THE OPTIMIZED RAYLEIGH–RITZ METHOD

Since the outer boundary of the plate is subjected to a uniformly applied pressure  $p_0$  the radial stress resultant  $N(\bar{r})$  is given by the classical Lamé solution

$$N(\bar{r}) = \frac{N_o}{1 - (b/a)^2} [1 - (\bar{r}/b)^2] \quad (1)$$

where  $N_o = ph_0$ .

Determination of the critical buckling load is defined by minimization of the governing functional

$$J(W) = \int_a^b D(\bar{r}) \left[ \left( W'' + \frac{W'}{\bar{r}} \right)^2 - 2(1-\nu) \frac{W'W''}{\bar{r}} \right] \bar{r} d\bar{r} - \int_a^b N(\bar{r}) W'^2 \bar{r} d\bar{r} \quad (2)$$

Fig. 1. Annular plate: elastic stability analysis.

subject to appropriate boundary conditions.

Introducing the dimensionless variable  $r = \rho/a$  and substituting in Equation (2) one obtains

$$\frac{a^2}{D_0} J(W) = \int_{r_b}^1 g(r) \left[ \left( W'' + \frac{W'}{r} \right)^2 - 2(1-\nu) \frac{W'W''}{r} \right] r dr - \frac{\lambda}{1-r_b^2} \int_{r_b}^1 \left( 1 - \frac{r_b^2}{r^2} \right) W'^2 r dr \quad (3)$$

where

$$r_b = \frac{b}{a}, D_0 = D(1), D(r) = D_0 g(r), \lambda = \frac{N_0 a^2}{D_0}$$

In the case of a simply supported edge the governing boundary conditions are

$$\begin{cases} W(1) = 0 \\ W''(1) + \nu W'(1) = 0 \end{cases} \quad (4a,b)$$

while for a clamped edge one must comply the essential boundary conditions

$$\begin{cases} W(1) = 0 \\ W'(1) = 0 \end{cases} \quad (5a,b)$$

Consider now the case of a circular, annular plate of discontinuously varying thickness, Fig. 1a. One has

$$g(r) = \begin{cases} \rho_h^3, & r_b \leq r \leq r_c, (r_c = c/a) \\ 1 & r_c < r < 1 \end{cases} \quad (6)$$

On the other hand, when the thickness varies linearly with the radial variable  $g(r)$  results

$$g(r) = \left[ \rho_h + \frac{1 - \rho_h}{1 - r_b} (r - r_b) \right]^3 \quad (7)$$

It is quite convenient to approximate the displacement amplitude  $W(r)$  by means of a summation of simple polynomial coordinate functions (Laura *et al.*, 1975).

$$W \cong W_\alpha = \sum_{j=1}^J C_j \psi_j(r) \quad (8)$$

where

$$\psi_j(r) = (\alpha_j r^p + \beta_j r^2 + 1) r^{j-1}$$

The  $\alpha_j$ s and  $\beta_j$ s are determined substituting each coordinate function in the governing outer boundary conditions. The exponential parameter  $p$  allows for minimization of the calculated eigenvalue (Laura, 1995).

Substituting Equation (8) in Equation (3) and requiring that the functional be a minimum with respect to the  $C_j$ s one obtains

$$\frac{\partial^2 J}{\partial C_i^2} = \sum_j \left\{ \int_{r_b}^1 \left( \psi_j''(r) \left( \psi_i''(r) + \frac{\psi_i'(r)}{r} \right) \left( \psi_j''(r) + \frac{\psi_j'(r)}{r} \right) \right. \right. \\ \left. \left. - \frac{1-\nu}{r} (\psi_j'' \psi_i' + \psi_j' \psi_i'') r dr - \frac{\lambda}{1-r_b^2} \int_{r_b}^1 \left( 1 - \frac{r_b^2}{r^2} \right) \psi_j' \psi_i' r dr \right) C_j = 0; \right. \quad (9) \\ \left. i = 1, 2, 3 \right.$$

The non-triviality condition leads to a secular determinant in  $\lambda$  and the lowest root is the desired critical buckling parameter.

Clearly one could construct polynomial coordinate functions, each one with two additional terms, in such a manner as to satisfy also the natural boundary conditions at the inner edge. However this will render the procedure lengthier and as it will shown in the next section the proposed approximate approach yields good engineering accuracy with a minimum amount of labour.

### 3. FINITE ELEMENT SOLUTION

The numerical results have been obtained using SAMCEF (1994) finite element code using hybrid elements of triangular and rectangular shape (elements type 55 and 56 of the SAMCEF Library). The number of elements varied in accordance with the ratio  $b/a$  (for  $b/a=0.1$  the mesh of half of the plate contained 661 elements).

#### 4. NUMERICAL RESULTS

All calculations have been performed making  $J=3$  in Equation (8).

Fig. 2a and Fig. 2b depict comparisons of values of  $N_0 a^2/D_0$  for simply supported and clamped annular plates at the outer boundary, with results available in the literature for  $\nu=1/3$ . Good engineering agreement is shown to exist.

Table 1, Table 2, Table 3, Table 4, Table 5, Table 6, Table 7, Table 8, and Table 9 contain values of  $N_0 a^2/D_0$  for annular plates with outer edge simply supported while Table 10, Table 11, Table 12, Table 13, Table 14, Table 15, Table 16, Table 17 and Table 18 show values of the buckling coefficient for the clamped outer edge situation for the configuration corresponding to Fig. 1a, including the uniform thickness case (Table 1 and Table 10).

The eigenvalues have been determined for Poisson's ratio equal to 0.2, 0.3, 0.33 and 0.40;  $h_1/h_0=1, 0.8$  and  $0.6$ ;  $b/a=0.1, 0.2 \dots 0.7$  and  $c/a=0.2, 0.3 \dots 0.8$ . They are computed using the optimized Rayleigh–Ritz method and in the cases of Table 1, Table 3, Table 7,

Table 10, Table 12 and Table 16 some values have been determined using the finite element method. Since the analytical formulation yields upper bounds it is concluded that in the case of Table 3 they are more accurate than those obtained by means of the finite element method for  $b/a=0.4$  and  $c/a=0.5$  and  $0.8$ ; and for  $b/a=0.7$  and  $c/a=0.8$ . Similarly:

for  $b/a=0.4$ ,  $c/a=0.5$  and  $0.8$  (Table 7);  $b/a=0.3$  and  $c/a=0.4$  (Table 12); and  $b/a=0.3$  and  $c/a=0.4$  (Table 16).

In the case of Table 16 the analytical approach yields a value of  $N_0 a^2/D_0$  which is, apparently, extremely high for  $b/a=0.5$  and  $c/a=0.8$ .

The agreement between both sets of values is, in general, quite good for the remaining situations.

Table 19 presents buckling coefficients for an annular plate which is simply supported at the outer boundary when the thickness varies linearly, Fig. 1b, while Table 20 deals with the case of an outer clamped edge.

It is important to emphasize the fact that Poisson's ratio has considerable weight upon the values of the buckling coefficient, specially when the outer edge is simply supported, i.e. in the case of Table 1 the buckling coefficient increases in about 10% when  $\nu$  varies from 0.20 to 0.40 for  $b/a=0.1$  while it decreases in 10% for  $b/a=0.7$  for the same variation of  $\nu$ .

The proposed approach is also applicable when the outer edge is elastically restrained against rotation. In this case condition 4(b) is replaced by

$$\frac{dW}{dr}(1) = -\varnothing D_o[W''(1) + \nu W'(1)] \quad (10)$$

where  $\varnothing$ : edge flexibility coefficient. When  $\varnothing \rightarrow 0$  the edge is rigidly clamped and when  $\varnothing \rightarrow \infty$  one has the simply supported condition.

Table 19. Buckling coefficient, continuous varying thickness. External boundary simply supported.

	Values of $b/a$						
	0.1	0.2	0.3	0.4	0.5	0.6	0.7
$h_1/h_0$							$\nu=0.2$
0.8	2.737	2.542	2.177	1.968	1.812	1.694	1.601
0.6	1.885	1.660	1.480	1.354	1.263	1.196	1.145
							$\nu=0.3$
0.8	2.860	2.502	2.169	1.929	1.757	1.630	1.533
0.6	1.927	1.657	1.450	1.310	1.213	1.143	1.090
							$\nu=0.33$
0.8	2.892	2.509	2.158	1.909	1.733	1.604	1.506
0.6	1.936	1.651	1.435	1.291	1.193	1.122	1.069
							$\nu=0.4$
0.8	2.962	2.512	2.116	1.847	1.662	1.529	1.429
0.6	1.950	1.626	1.388	1.236	1.135	1.064	1.012

Table 20. Buckling coefficient, continuous varying thickness. External boundary clamped.

	Values of $b/a$				
	0.1	0.2	0.3	0.4	0.5
$h_1/h_0$					$\nu=0.2$
0.8	10.710	10.842	12.308	15.662	22.159
0.6	7.524	7.744	9.184	12.150	17.680
					$\nu=0.3$
0.8	10.419	10.345	11.667	14.924	21.260
0.6	7.191	7.295	8.655	11.541	16.962
					$\nu=0.33$
0.8	10.325	10.185	11.464	14.687	20.982
0.6	7.086	7.154	8.490	11.353	16.724
					$\nu=0.4$
0.8	10.091	9.787	10.967	14.115	20.318
0.6	6.829	6.812	8.095	10.907	16.223
